

RESEARCH REPORT

My theoretical hypothesis was that Star wars newer films are worst qualified than olders.

I calculated first descriptive data to check mean and SD. So, rating mean of Star Wars films was $7,26 \pm 1,49$.

I compared ratings of films with year of publication, trying to understand its evolution. Using data analysis explained in preregistration, we could discover a reversal correlation between year of film and rating of it (-0,576). However, effect size was too small to consider this result like a true effect.

Finally, it is necessary to increase the number of variable to analyze this likely reversal correlation on Star Wars films.
