Two sample Student's t-test #1

July 24, 2009

By [Todos Logos](#)

Like Share 32 Tweet Share

(This article was first published on [Statistic on aiR](#), and kindly contributed to [R-bloggers](#))

t-Test to compare the means of two groups under the assumption that both samples are random, independent, and come from normally distributed population with unknown but equal variances

Here I will use the same data just seen in a [previous post](#). The data are given below:

A: 175, 168, 168, 190, 156, 181, 182, 175, 174, 179
B: 185, 169, 173, 173, 188, 186, 175, 174, 179, 180

To solve this problem we must use to a Student's t-test with two samples, assuming that the two samples are taken from populations that follow a Gaussian distribution (if we cannot assume that, we must solve this problem using the non-parametric test called **Wilcoxon-Mann-Whitney test**; we will see this test in a future post). Before proceeding with the *t-test*, it is necessary to evaluate the sample variances of the two groups, using a **Fisher's F-test** to verify the *homoskedasticity (homogeneity of variances)*. In R you can do this in this way:

```
a = c(175, 168, 168, 190, 156, 181, 182, 175, 174, 179)
b = c(185, 169, 173, 173, 188, 186, 175, 174, 179, 180)

var.test(a,b)

      F test to compare two variances

data: a and b
F = 2.1028, num df = 9, denom df = 9, p-value = 0.2834
alternative hypothesis: true ratio of variances is not equal to 1
95 percent confidence interval:
 0.5223017 8.4657950
sample estimates:
ratio of variances
2.102784
```

We obtained p-value greater than 0.05, then we can assume that the two variances are homogeneous. Indeed we can compare the value of F obtained with the tabulated value of F for $\alpha = 0.05$, degrees of freedom of numerator = 9, and degrees of freedom of denominator = 9, using the function `qf(p, df.num, df.den)`:

```
qf(0.95, 9, 9)
[1] 3.178893
```

Note that the value of F computed is less than the tabulated value of F, which leads us to accept the null hypothesis of homogeneity of variances.

NOTE: The F distribution has only one tail, so with a confidence level of 95%, $p = 0.95$. Conversely, the *t-distribution* has two tails, and in the R's function `qt(p, df)` we insert a value $p = 0.975$ when you're testing a two-tailed alternative hypothesis.

Then call the function `t.test` for homogeneous variances (`var.equal = TRUE`) and independent samples (`paired = FALSE`; you can omit this because the function works on independent samples by default) in this way:

```
t.test(a,b, var.equal=TRUE, paired=FALSE)
```

Two Sample t-test

```
data: a and b
t = -0.9474, df = 18, p-value = 0.356
alternative hypothesis: true difference in means is not equal to 0
95 percent confidence interval:
 -10.93994 4.13994
sample estimates:
mean of x mean of y
 174.8      178.2
```

We obtained p-value greater than 0.05, then we can conclude that the averages of two groups are significantly similar. Indeed the value of t-computed is less than the tabulated t-value for 18 degrees of freedom, which in R we can calculate:

```
qt(0.975, 18)
[1] 2.100922
```

This confirms that we can accept the null hypothesis H_0 of equality of the means.
