

TUTORIAL 10: Topological sort  
=====

Instance: Directed acyclic graph (DAG)  
Question: What is an ordering of vertices  $1, \dots, |V|$  such that for every edge  $(u,v)$ ,  $u$  appears before  $v$  in the ordering?

Algorithm:  
TOPOLOGICAL-SORT( $G$ )  
1 call DFS( $G$ ) to compute finishing times  $f[v]$  for each vertex  $v$   
2 as each vertex is finished, insert it onto the front of a linked list  
3 return the linked list of vertices

Example of topological sort:  
Demonstrate an example of topological sort using a directed graph with about 6 vertices. I've drawn one possible example to show. (The dots represent the pointed end of the arrow.)

Running time of topological sort:  $\Theta(n + m)$   
Why? Depth first search takes  $\Theta(n + m)$  time in the worst case, and inserting into the front of a linked list takes  $\Theta(1)$  time.

Edge classification:  
-----  
There are four types of edges in a graph  $G$ . Run DFS on  $G$  and consider the resulting depth-first forest:

- 1) Tree edges = edges in the depth-first forest.
- 2) Back edges = nontree edges  $(u, v)$  in  $G$  connecting a vertex  $u$  to an ancestor  $v$  in a depth-first tree.
- 3) Forward edges = nontree edges  $(u, v)$  connecting a vertex  $u$  to a descendant  $v$  in a depth-first tree.
- 4) Cross edges = all other edges.
  - a) nontree edges  $(u, v)$  connecting vertices in the same depth-first tree, as long as one vertex is not an ancestor of the other, and
  - b) nontree edges  $(u, v)$  connecting vertices in different depth-first trees.

Draw a picture to show the different types of edges

Notice: If there is a back edge, there must be a cycle in  $G$   
Why? If there is a back edge  $(u,v)$ , then vertex  $v$  is an ancestor of vertex  $u$  in the depth-first forest. Thus, there is a path from  $v$  to  $u$  and an edge from  $u$  to  $v$ .  
-> there is a cycle

Theorem 22.12  
TOPOLOGICAL-SORT( $G$ ) produces a topological sort of a directed acyclic graph  $G$ .

Proof:  
  
First run DFS on  $G$  to determine the finishing time for each vertex.

Claim: for any  $u,v \in V$ , if  $u \neq v$  and  $(u,v) \in E$ , then  $f[v] < f[u]$ .

Proof of claim:  
Consider when the edge  $(u,v)$  is explored by the DFS.

- i) If  $v$  is gray, then  $v$  is an ancestor of  $u$ 
  - a) Thus  $(u,v)$  is a back edge
  - >  $G$  has a cycle
  - But  $G$  is acyclic, so  $v$  cannot be gray
- ii) If  $v$  is white, it becomes a descendant of  $u$ , and so  $f[v] < f[u]$ 
  - i.e. we finish examining the descendants of  $v$  before those of  $u$
- iii) If  $v$  is black, it is already finished.
  - >  $f[v]$  is already set
  - We are still exploring descendants of  $u$ , so  $f[u]$  is not set
  - >  $f[v] < f[u]$

So the claim is true: if  $(u,v) \in E$ ,  $f[v] < f[u]$ .

TOPOLOGICAL-SORT( $G$ ) places vertices in a linked list from highest to lowest finishing time. Therefore, if  $(u,v) \in E$ ,  $u$  will be before  $v$  in the list.

Theorem 22.9  
-----  
In a depth-first forest of a (directed or undirected) graph  $G = (V, E)$ , vertex  $v$  is a descendant of vertex  $u$  if and only if at the time  $d[u]$  that the DFS discovers  $u$ , vertex  $v$  can be reached from  $u$  along a path consisting entirely of white vertices.

Proof:  
-----  
Direction #1: If vertex  $v$  can be reached from  $u$  along a path consisting entirely of white vertices at time  $d[u]$ , then vertex  $v$  is a descendant of vertex  $u$  in the depth-first forest.

We will prove direction #1 using a proof by contradiction:  
Without loss of generality, let  $v$  be the first vertex in the path of white vertices which does not become a descendant of  $u$ .

Let  $w$  be the predecessor of  $v$  in the path  
 $w$  is either a descendant of  $u$  or  $u$  itself ( $f[w] \leq f[u]$ )  
 $v$  must be discovered after  $u$ , since  $v$  is still white ( $d[v] > d[u]$ )  
 $v$  must be discovered before  $w$  is finished ( $d[v] < f[w]$ )  
Thus:  $d[u] < d[v] < f[w] \leq f[u]$

But: if  $v$  is discovered after  $u$ ,  $v$  must be finished before  $u$  ( $f[v] < f[u]$ )  
Thus:  $d[u] < d[v] < f[v] < f[u]$   
->  $v$  is a descendant of  $u$

Direction #2: If vertex  $v$  is a descendant of vertex  $u$  in the depth-first forest, then vertex  $v$  can be reached from  $u$  along a path consisting entirely of white vertices at time  $d[u]$ .

We will prove direction #2 using a direct proof:  
Let  $v$  be a descendant of  $u$  in the depth-first tree.  
Let  $w$  be any vertex on the path between  $u$  and  $v$  in the depth-first tree.  
->  $w$  is a descendant of  $u$   
->  $d[w] > d[u]$   
->  $w$  is white at time  $d[u]$

Lemma 22.11  
-----  
A directed graph  $G$  is acyclic iff a DFS of  $G$  yields no back edges.

Proof:  
  
Direction #1: If directed graph  $G$  is acyclic, then a DFS of  $G$  yields no back edges.  
Contrapositive: If a DFS of  $G$  yields some back edge, then the directed graph  $G$  contains a cycle.

We showed this earlier.

Direction #2: If the a DFS of  $G$  yields no back edges, then the directed graph  $G$  is acyclic.  
Contrapositive: If the graph contains a cycle, then the DFS of  $G$  yields a back edge.

Proof of the contrapositive:  
Suppose that  $G$  contains a cycle  $c$ .  
Let  $v$  be the first vertex discovered in  $c$  during the DFS.

Let  $u$  be the parent of  $v$  in the cycle.  
Since  $v$  is the first to be discovered in  $c$ , the path from  $v$  to  $u$  is formed by all white vertices.

By the white-path theorem (Theorem 22.9), vertex  $u$  is a descendant of vertex  $v$  iff at time  $d[v]$ , vertex  $v$  can be reached from  $u$  along a path consisting entirely of white vertices.  
->  $u$  is a descendant of  $v$   
-> edge  $(u,v)$  is a back edge.
