Package 'yhat'

September 16, 2013

Type Package

Title Interpreting Regression Effects

Version 2.0-0

Date 2013-09-10

Author Kim Nimon <kim.nimon@gmail.com>, Fred Oswald, and J. Kyle Roberts.

Maintainer Kim Nimon <kim.nimon@gmail.com>

Depends R (>= 2.7.0)

Imports yacca, miscTools, plotrix, boot

Suggests MBESS

Description The purpose of this package is to provide methods to interpret multiple
linear regression and canonical correlation results including beta weights,structure coeffi-
cients,validity coefficients, product measures, relative weights, all-possible-subsets regres-
sion,dominance analysis, commonality analysis, and adjusted effect sizes.

License GPL (>= 2)

yhat-package	*Interpreting Regression Effects*

Description

The purpose of this package is to provide methods to interpret multiple linear regression and canonical correlation results including beta weights, structure coefficients, validity coefficients, product measures, relative weights, all-possible-subsets regression, dominance analysis, commonality analysis, and adjusted effect sizes.

Details

Package:	yhat
Type:	Package
Version:	2.0-0
Date:	2013-09-10
License:	GPL (>= 2)
LazyLoad:	yes

aps *All Possible Subsets Regression*

Description

The function runs all possible subsets regression and returns data needed to run commonality and dominance analysis.

Usage

```
aps(dataMatrix, dv, ivlist)
```

Arguments

dataMatrix	Dataset containing the dependent and independent variables
dv	The dependent variable named in the dataset
ivlist	List of independent variables named in the dataset

Details

Function returns all possible subset information that is used by commonality and dominance. If data are missing, non-missing data are eliminated based on listwise deletion for full model.

Value

`ivID`	Matrix containing independent variable IDS.
`PredBitMap`	All possible subsets predictor bit map.
`apsBitMap`	Index into all possible subsets predictor bit map.
`APSMatrix`	Table containing the number of predictors and Multiple R^2 for each possible set of predictors.

Examples

```
## APS regression predicting miles per gallon based
## on vehicle weight, type of
## carborator, & number of engine cylinders
   apsOut<-aps(mtcars,"mpg",list("wt","carb","cyl"))

## APS regression predicting paragraph comprehension based
## on thre verbal tests: general info, sentence comprehension,
## & word classification

## Use HS dataset in MBESS
   require ("MBESS")
   data(HS.data)
## APS
   apsOut<-aps(HS.data,"paragrap",list("general","sentence",
                                        "wordc"))
```

---

boot.yhat   *Bootstrap metrics produced from /codecalc.yhat*

Description

This function is input to `boot` to bootstrap metrics computed from `calc.yhat`.

Usage

```
boot.yhat(data, indices, lmOut,regrout0)
```

Arguments

`data`	Original dataset
`indices`	Vector of indices which define the bootstrap sample
`lmOut`	Ouput of /codelm
`regrout0`	Output of /codecalc.yhat

Details

This function is input to `boot` to bootstrap metrics computed from `calc.yhat`.

Value

The output of `boot.yhat` when used in conjunction with `boot` is of class boot and is not further described here. The output is designed to be useful as input for `booteval.yhat`

```

---

booteval.yhat   *Evaluate bootstrap metrics produced from /codecalc.yhat*

Description

This function evaluates the bootstrap metrics produced from /codeboot.yhat.

Usage

```
booteval.yhat(regrOut, boot.out, bty, level, prec)
```

Arguments

regrOut	Output from `calc.yhat`
boot.out	Output from boot in conjunction with `boot.yhat`
bty	Type of confidence interval. Only types "perc", "norm", "basic", and "bca" supported.
level	Confidence level (e.g., .95)
prec	Integer indicating number of decimal places to be used.

Details

This function evaluates the bootstrap metrics produced from `boot.yhat`.

Value

Confidence intervals are reported for predictor and all possible subset metrics as well as differences between appropriate predictors and all possible subset metrics. The function also output the means, standard errors, probabiltites, and reproducibility metrics for the dominance comparisons. Means and standard deviations are reported for Kendall's tau correlation between sample predictor metrics and the bootstrap statistics of like metrics.

combCIpm	Upper and lower CIs for predictor metrics
lowerCIpm	Lower CIs for predictor metrics
upperCIpm	Upper CIs for predictor metrics
combCIaps	Upper and lower CIs for APS metrics
lowerCIaps	Lower CIs for APS metrics
upperCIaps	Upper CIs for APS metrics
domBoot	Dominance analysis bootstrap results
tauDS	Descriptive statistics for Kendall's tau
combCIpmDiff	Upper and lower CIs for differences between predictor metrics
lowerCIpmDiff	Lower CIs for differences between predictor metrics
upperCIpmDiff	Upper CIs for differences between predictor metrics

combCIapsDiff   Upper and lower CIs for differences between APS metrics

lowerCIapsDiff Lower CIs for differences between APS metrics

upperCIapsDiff Upper CIs for differences between APS metrics

combCIincDiff   Upper and lower CIs for differences between incremental validity metrics

lowerCIincDiff Lower CIs for differences between incremental validity metrics

upperCIincDiff Upper CIs for differences between incremental validity metrics

```

---

calc.yhat   *More regression indices for lm class objects*

Description

Reports beta weights, validity coefficients, structure coefficients, product measures, commonality analysis coefficients, and dominance analysis weights for lm class objects.

Usage

```
calc.yhat(lm.out,prec=3)
```

Arguments

lm.out	lm class object
prec	level of precision for rounding, defaults to 3

Details

Takes the lm class object and reports beta weights, validity coefficients, structure coefficients, product measures, commonality analysis coefficients, and dominance analysis weights.

Value

PredictorMetrics
              Predictor metrics associated with lm class object
OrderedPredictorMetrics
              Rank order of predictor metrics
PairedDominanceMetrics
              Dominance analysis for predictor pairs
APSRelatedMetrics
              APS metrics associated with lm class object

---

canonCommonality	*Commonality Coefficents for Canonical Correlation*

Description

The `canonCommonality` function produces commonality data for both canonical variables sets. Variables in a given canonical set are used to partition the variance of the canonical variates produced from the *other* canonical set and vica versa. Commonality data is supplied for the number of canonical functions requested.

Usage

```
canonCommonality(A, B, nofns = 1)
```

Arguments

A   Matrix containing variable set A

B   Matrix containing variable set B

nofns   Number of canonical functions to analyze

Details

The function `canonCommonality` has two required arguments and one optional argument. The first two arguments contain the two variable sets. The third argument is optional and defnes the number of canonical functions to analyze. Unless specifed, the number of canonical functions defaults to 1.

The function `canonCommonality` calls a function `canonVariate` to decompose canonical varites twice: the first time for the variable set identified in the first argument, the second time for the variable set identified in the second argument.

Value

The function `canonCommonality` returns commonality data for both canonical variable sets. For the number of functions requested, both canonical variates are analyzed. For each canonical variate analyzed, two tables are returned. The first table lists the commonality coefficients and their contribution to the total effect, while the second table lists the unique and common effects for each regressor. The function returns the resulting output ordering the output according to the function's paramaeters.

   MATH_FUND<-HS.data[,c("numeric","arithmet","addition")]
## Perform Commonality Coefficient Analysis
   canonCommonData<-canonCommonality(MATH_FUND,MATH_REASON,1)
   detach(HS.data)
```

---

canonVariate	*Canonical Commonality Analysis*

Description

The `canonCommonality` function produces commonality data for a given canonical variable set. Using the variables in a given canonical set to partition the variance of the canonical variates produced from the *other* canonical set, commonality data is supplied for the number of canonical functions requested.

Usage

```
canonVariate(A, B, nofns)
```

Arguments

A	Matrix containing variable set A
B	Matrix containing variable set B
nofns	Number of canonical functions to analyze

Details

For each canonical function, `canonVariate`: (a) creates a dataset that combines the matrix of variables for a given canonical set and the canonicate variate for the *other* canonical set; (b) calls `commonalityCoefficients`, passing the dataset, the name of the canonical variate, and the names of the variates in a given canonical set; (c) saves resultant output.

Value

The function `canonVariate` returns commonality data for the canonical variable set input. For the number of functions requested, two tables are returned. The first table lists the commonality coefficients for each canonical function together with its contribution to the total effect, while the second table lists the unique and common effects for each regressor.

Note

This function is internal to [canonCommonality](#), called during runtime and passed the appropriate parameters. This is not an end-user function.

ci.yhat   *Compute CI*

Description

This function retrieves the proper elements from boot.ci.

Usage

```
ci.yhat(bty, CI)
```

Arguments

bty   Type of CI

CI   CI

Details

This function retrieves the proper elements from boot.ci.

Value

This function returns the proper elements from boot.ci.

Note

This function is internal to the yhat package and not intended to be an end-user function.

Author(s)

Kim Nimon <kim.nimon@gmail.com>

---

combCI   *Combine upper and lower confidence intervals*

Description

This function combines upper and lower confidence intervals along with sample statistics and optionally stars intervals that do not contain 0.

Usage

```
combCI(lowerCI, upperCI, est, star=FALSE )
```

Arguments

lowerCI   Lower CI

upperCI   Upper CI

est   Estimate

star   Boolean to indicate whether CIs that do not contain zero should be starred.

Details

This function evaluates the bootstrap metrics produced from /codeboot.yhat.

Value

Returns estimate with confidence interval in ( ). Optionally, confidence interval not containing 0 is starred.

Note

This function is internal to the yhat package and not intended to be an end-user function.

commonality   *Commonality Analysis*

Description

This function conducts commonality analyses based on an all-possible-subsets regression.

Usage

```
commonality(apsOut)
```

Arguments

apsOut   Output from /codeaps

Details

This function conducts commonality analyses based on an all-possible-subsets regression.

Value

The function returns a matrix containing commonality coefficients and percentage of regression effect for each each possible set of predictors.

commonalityCoefficients

Commonality Coefficents

Description

Commonality Coefficients returns a list of two tables. The first table CC contains the list of commonality coefficients and the percent variance for each effect. The second CCTotByVar totals the unique and common effects for each independent variable.

Usage

```
    commonalityCoefficients(dataMatrix, dv, ivlist, imat=FALSE)
```

Arguments

dataMatrix	Dataset containing the dependent and independent variables
dv	The dependent variable named in the dataset
ivlist	List of independent variables named in the dataset
imat	Echo flag, default to FALSE

Details

When echo flag is true, transitional matrices during commonality coefficient calculation are sent to output window. Default for this option is false. When set to true, the intermediate matrices for each commonality coefficient and regression combinations are printed in the output window.

Value

CC	Matrix containing commonality coefficients and percentage of variance for each effect.
CCTotalByVar	Table of unique and common effects for each independent variable.

dombin   *Dominance Analysis*

Description

For each level of dominance and pairs of predictors in the full model, this function indicates whether a predictor "x1" dominates "x2", predictor "x2" dominates "x1", or that dominance cannot be established between predictors.

Usage

```
dombin(domOut)
```

Arguments

domOut   Output from /codedominance

Details

For each level of dominance and pairs of predictors in the full model, this function indicates whether a predictor "x1" dominates "x2", predictor "x2" dominates "x1", or that dominance cannot be established between predictors.

Value

The function return a matrix that contains dominance level decisions (complete, conditional, and general) for each pair of predictors in the full model.

dominance   *Dominance Weights*

Description

Computes dominance weights including conditional and general.

Usage

```
dominance(apsOut)
```

Arguments

apsOut   Output from /codeaps

Details

Provides full dominance weights table that are used to compute conditional and general dominance weights as well as reports conditional and general dominance weights.

Value

DA   Dominance analysis table

CD   Conditional dominance weights

GD   General dominance weights

effect.size   *Effect Size Computation for lm*

Description

Creates adjusted effect sizes for linear regression.

Usage

```
effect.size(lm.out)
```

Arguments

lm.out   Output from lm class object

Details

The function `effect.size` produces a family of effect size corrections for the R-squared metric produced from an `lm` class object. Suggestions for recommended correction are supplied, based on Yin and Fan (2001).

Value

Returns adjusted R-squared metric.

Author(s)

J. Kyle Roberts <kyler@smu.edu>

detach(HS.data)
```

genList   *Generate List R^2 Values*

Description

Use the bitmap matrix to generate the list of *R^2* values needed.

Usage

```
genList(ivlist, value)
```

Arguments

ivlist   List of independent variables in dataset

value   Number of variables

Details

Returns the number of *R^2* values that will be calculated in output tables.

Value

Returns `newlist` from generate list function call.

Note

This function is internal to commonalityCoefficients, called during runtime and passed the appropriate parameters. This is not an end-user function.

Author(s)

Kim Nimon <kim.nimon@gmail.com>

odd   *isOdd Function*

Description

Function receives value and returns true if value is odd.

Usage

```
odd(val)
```

Arguments

val   Value to check

Details

Determines value of parameter in argument.

Value

Returns true when value checked is odd. Otherwise, function returns a value false.

Note

This function is internal to commonalityCoefficients, called during runtime and passed the appropriate parameters. This is not an end-user function.

plotCI.yhat   *Plot CIs from yhat*

Description

This function plots CIs that have been produced from /codebooteval.yhat.

Usage

```
plotCI.yhat(sampStat, upperCI, lowerCI, pid=1:ncol(sampStat), nr=2, nc=2)
```

Arguments

sampStat	Set of sample statistics
upperCI	Set of upper CIs
lowerCI	Set of lower CIs
pid	Which set of Metrics to plot (default to all)
nr	Number of rows (default = 2)
nc	Number of columns(default = 2)

Details

This function plots CIs that have been produced from /codebooteval.yhat.

Value

This returns a plot of CIs that have been produced from /codebooteval.yhat.

regr   *Regression effect reporting for lm class objects*

Description

The regr reports beta weights, standardized beta weights, structure coefficients, adjusted effect sizes, and commonality coefficients for lm class objects.

Usage

```
regr(lm.out)
```

Arguments

lm.out   lm class object

Details

The function regr takes the lm class object and reports beta weights, standardized beta weights, structure coefficients, adjusted effect sizes, and commonality coefficients for lm class objects.

Value

LM_Output   The summary of the output from the lm class object

Beta_Weights   Beta weights for the regression effects

Structure_Coefficients
                Structure coefficients for the regression effects

Commonality_Data
                Commonality coefficients for the regression effects. The output only produces a parsed version of CCdata

Effect_Size   Adjusted effect size computations based on R^2 adjustments

rlw   *Relative Weights*

Description

The function computes relative weights.

Usage

```
rlw(dataMatrix, dv, ivlist)
```

Arguments

dataMatrix	Dataset containing the dependent and independent variables
dv	The dependent variable named in the dataset
ivlist	List of independent variables named in the dataset

Details

The function computes relative weights.

Value

The function returns relative weights for each predictor.

setBits   *Decimal to Binary*

Description

Creates the binary representation of n and stores it in the nth column of the matrix.

Usage

```
    setBits(col, effectBitMap)
```

Arguments

col   Column of matrix to represent in binary image

effectBitMap   Matrix of mean combinations in binary form

Details

Creates the binary representation of col and stores it in its associated column.

Value

Returns matrix effectBitMap of mean combinations in binary form.

Note

This function is internal to commonalityCoefficients, called during runtime and passed the appropriate parameters. This is not an end-user function.
