Your grade: 100%

Your latest: **100%** • Your highest: **100%** • To pass you need at least 80%. We keep your highest score.

Attention

Before starting this graded assignment, make sure that you have the output of the **Module 2 programming assignment** open. Some of the questions in this assignment use the output of the programming assignment.

1. Which of the following best explains the process of agglomerative hierarchical clustering? 1 / 1 point

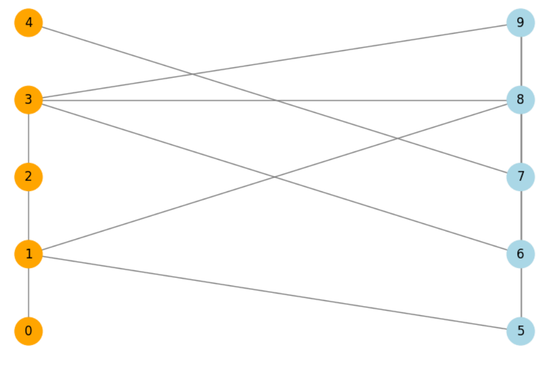

Nice work

2. Consider this graph. What is the **coverage** of this partition? Calculate to 3 decimal point. 1 / 1 point

Nice work

3. Consider this graph. Calculate the **performance** of this partition to 3 decimal points. 1 / 1 point

Nice work

4. How does the Label Propagation Algorithm (LPA) assign communities to nodes? 1 / 1 point

Nice work

5. In the last code block for this module's programming assignment, we used a community detection algorithm and identified the 18 teams that are in the same community as New Mexico. We then observed that all the teams in this community belong to two of the 13 conferences: Mountain West and Pacific Ten. 1 / 1 point

What might explain why the nodes/colleges in the community with New Mexico are all from the Mountain West and Pacific Ten Conferences?

Nice work

6. What does *modularity* measure in the context of community detection? 1 / 1 point

Nice work

7. What is a key advantage of the Label Propagation Algorithm (LPA)? 1 / 1 point

Nice work

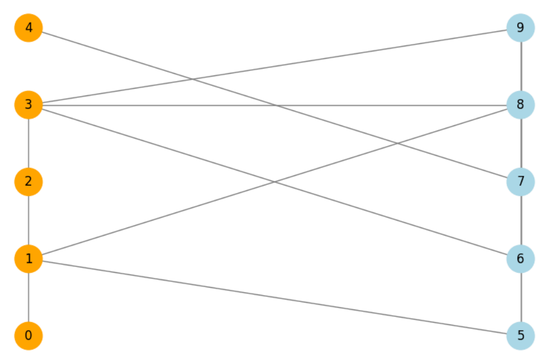

8. What is the primary method used by the Girvan-Newman algorithm to detect communities? 1 / 1 point

Nice work

9. What does *performance* measure in the context of community detection? 1 / 1 point

Nice work

10. Consider this graph. What is the **separability** of this partition? Calculate to 3 decimal point. 1 / 1 point

Nice work
